

# What the physics head sees

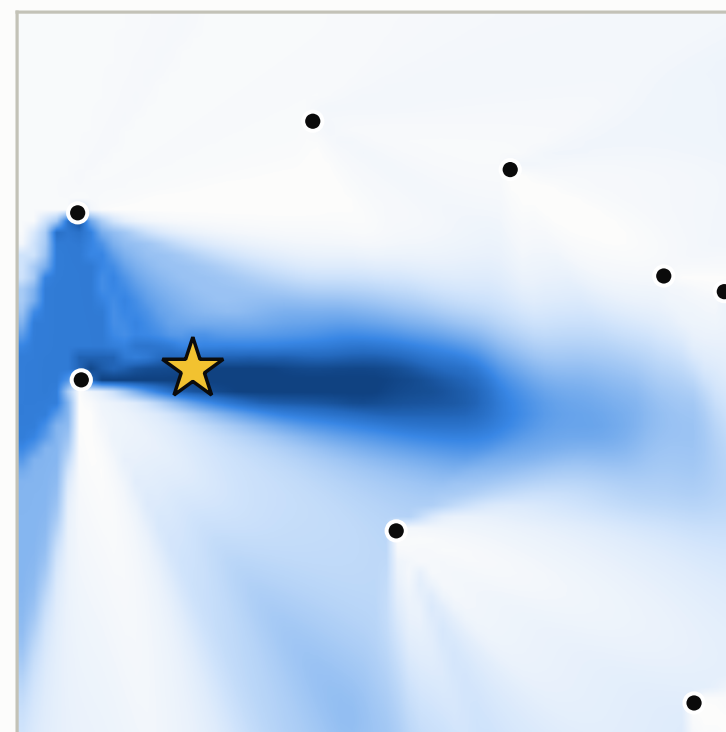

the four closed-form input maps for one held-out scenario (8 masts, 92 kg h<sup>-1</sup>), computed from measured wind only; maps B-E are the network's extra input

**A. What the sensors observed**

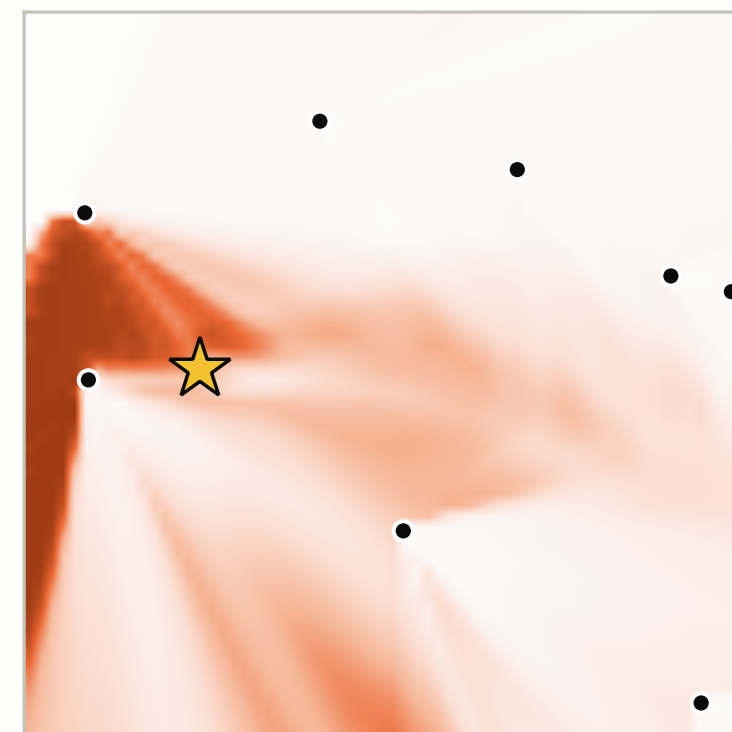

dot size = peak methane reading;  
arrow = measured wind

**B. Source evidence**

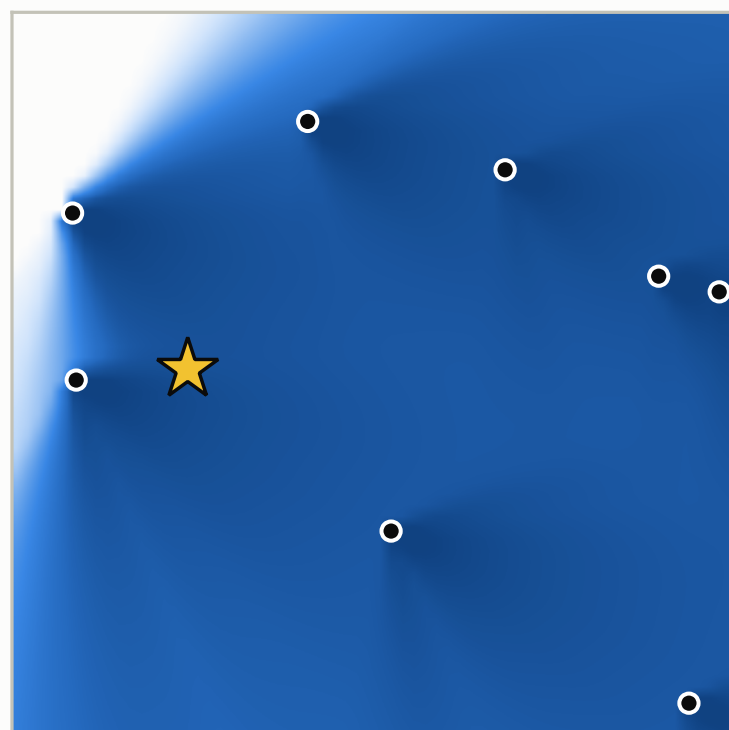

dark = a leak here explains  
the observed readings

**C. Wind sensitivity**

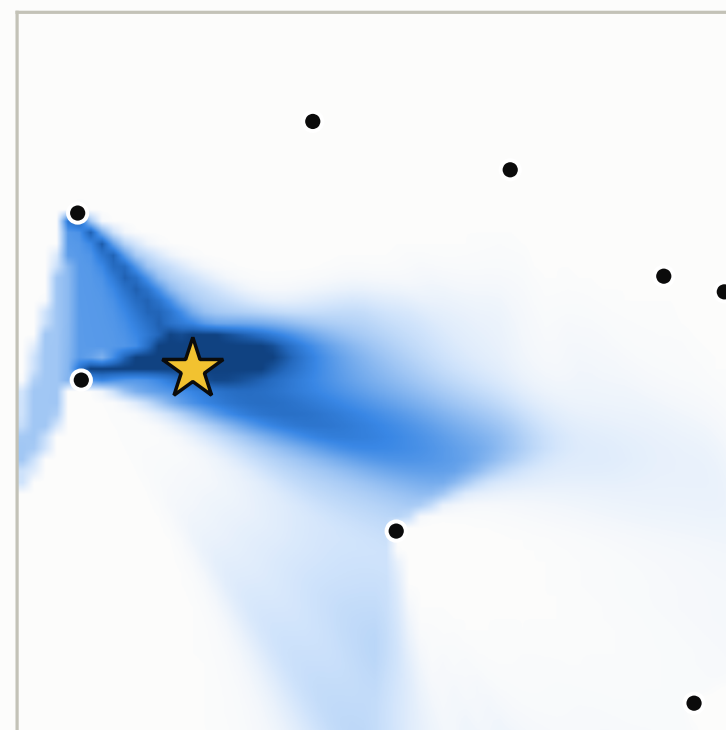

dark = evidence unstable  
under anemometer error

**D. Sensor visibility**

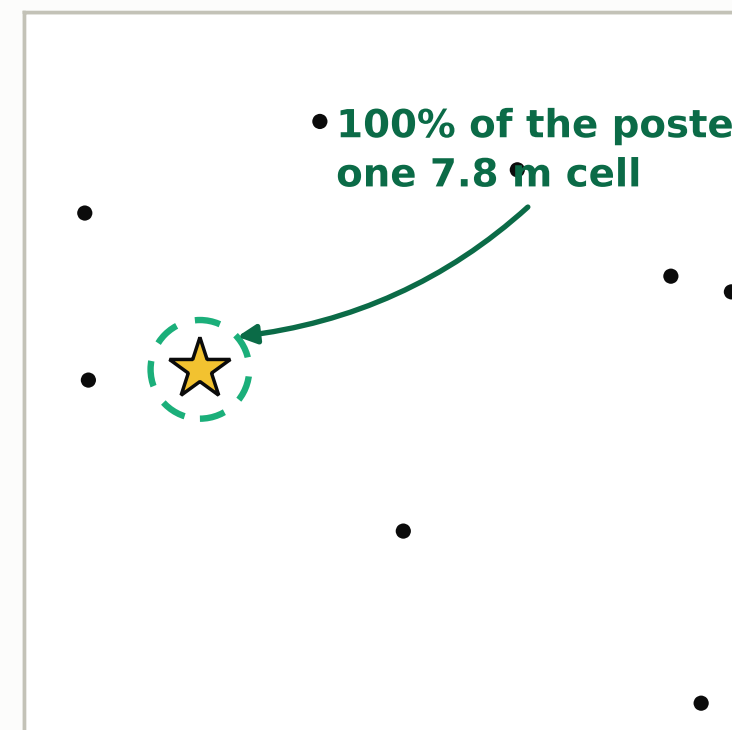

dark = a leak here would be  
seen by many masts

**E. Fit quality**

dark = plume model fits well  
after best-rate scaling

**F. Exact Bayes reference (known wind)**

with the true wind, the posterior collapses  
to one grid cell — wind error is the whole game

● sensor masts (8)    ★ true methane source
